MAXIM

4A, Low-Noise, High-Frequency, Step-Up DC-DC Converter

General Description

The MAX1709 sets a new standard of space savings for high-power, step-up DC-DC conversion. It delivers up to 20W at a fixed (3.3V or 5V) or adjustable (2.5V to 5.5V) output, using an on-chip power MOSFET from a +0.7V to +5V supply.

Fixed-frequency PWM operation ensures that the switching noise spectrum is constrained to the 600kHz fundamental and its harmonics, allowing easy postfiltering for noise reduction. External clock synchronization capability allows for even tighter noise spectrum control. Quiescent power consumption is less than 1mW to extend operating time in battery-powered systems.

Two control inputs (ONA, $\overline{ONB}$) allow simple push-on, push-off control through a single momentary pushbutton switch, as well as conventional on/off logic control. The MAX1709 also features programmable soft-start and current limit for design flexibility and optimum performance with batteries. The maximum RMS switch current rating is 10A. For a device with a lower current rating, smaller size, and lower cost, refer to the MAX1708 data sheet.

Applications

Routers, Servers, Workstations, Card Racks

Local 2.5V to 3.3V or 5V Conversion

Local 3.3V to 5V Conversion

3.6V or 5V RF PAs in Communications Handsets

Features

- **On-Chip 10A Power MOSFET**
- **5V, 4A Output from a 3.3V Input**
- **Fixed 3.3V or 5V Output Voltage or Adjustable (2.5V to 5.5V)**
- **Input Voltage Range Down to 0.7V**
- **Low Power Consumption**
  1mW Quiescent Power
  1µA Current in Shutdown Mode
- **Low-Noise, Constant Frequency Operation (600kHz)**
- **Synchronizable Switching Frequency (350kHz to 1000kHz)**

CLK/SEL Rise/Fall Time	(Note 8)			50	ns

Note 1: Output voltage is specified at 1A switch current I_{SW}, which is equivalent to approximately 1A × (V_{IN} / V_{OUT}) of load current.

Note 2: Load regulation is measured by forcing specified switch current and straight-line calculation of change in output voltage in external feedback mode. Note that the equivalent load current is approximately I_{SW} × (V_{IN} / V_{OUT}).

Note 3: Until undervoltage lockout is reached, the device remains in startup mode. Do not apply full load until this voltage is reached.

Note 4: Startup is tested with Figure 1's circuit. Output current is measured when both the input and output voltages are applied.

Note 5: Minimum operating voltage. The MAX1709 is bootstrapped and will operate down to a 0.7V input once started.

Note 6: Supply current is measured from the OUT pin to the output voltage (+3.3V). This correlates directly with actual input supply current but is reduced in value according to the step-up ratio and efficiency.

Note 7: ONA and $\overline{ONB}$ inputs have approximately 0.15V hysteresis.

Note 8: Guaranteed by design, not production tested.

Note 9: Specifications to -40°C are guaranteed by design, not production tested.

Pin Description

PIN	NAME	FUNCTION
1	ONA	On-Control Input. When ONA = high or $\overline{ONB}$ = low, the device turns on (Table 1).
2, 3, 4	LX	Drain of N-Channel Power Switch. Connect pins 2, 3, and 4 together. Connect external Schottky diode from LX to OUT.
5, 8	GND	Ground
6	SS/LIM	Soft-Start and/or Current-Limit Input. Connect a capacitor from SS/LIM to GND to control the rate at which the device reaches current limit (soft-start). To reduce the current limit from the preset values, connect a resistor from SS/LIM to GND (see *Design Procedure*). During shutdown, this pin is internally pulled to GND to discharge the soft-start capacitor.
7	REF	1.26V Voltage Reference Output. Bypass with a 0.22µF capacitor to GND. Maximum REF load is 50µA.
9	OUT	Output Voltage Sense Input. The device is powered from OUT. Bypass with a 0.1µF to PGND with less than 5mm trace length. Connect a 2Ω series resistor from the output filter capacitor to OUT (Figure 1).
10	FB	DC-DC Converter Feedback Input. Connect FB to GND for internally set output voltage (see $\overline{3.3}$/5 pin description). Connect a resistor-divider from the output to set the output voltage in the +2.5V to +5.5V range. FB regulates to +1.25V (Figure 4).
11, 12, 13	PGND	Power Ground, Source of N-Channel Power MOSFET Switch
14	$\overline{3.3}$/5	Output Voltage Selection Pin. When FB is connected to GND, the regulator uses internal feedback to set the output voltage. $\overline{3.3}$/5 = low sets output to 3.3V; $\overline{3.3}$/5 = high sets output to 5V. If an external divider is used at FB, connect $\overline{3.3}$/5 to ground.
15	CLK	Clock Input for the DC-DC Converter. Connect to OUT for internal oscillator. Optionally, drive with an external clock for external synchronization.
16	$\overline{ONB}$	Shutdown Input. When $\overline{ONB}$ = high and ONA = low, the device turns off (Table 1).

4A, Low-Noise, High-Frequency, Step-Up DC-DC Converter

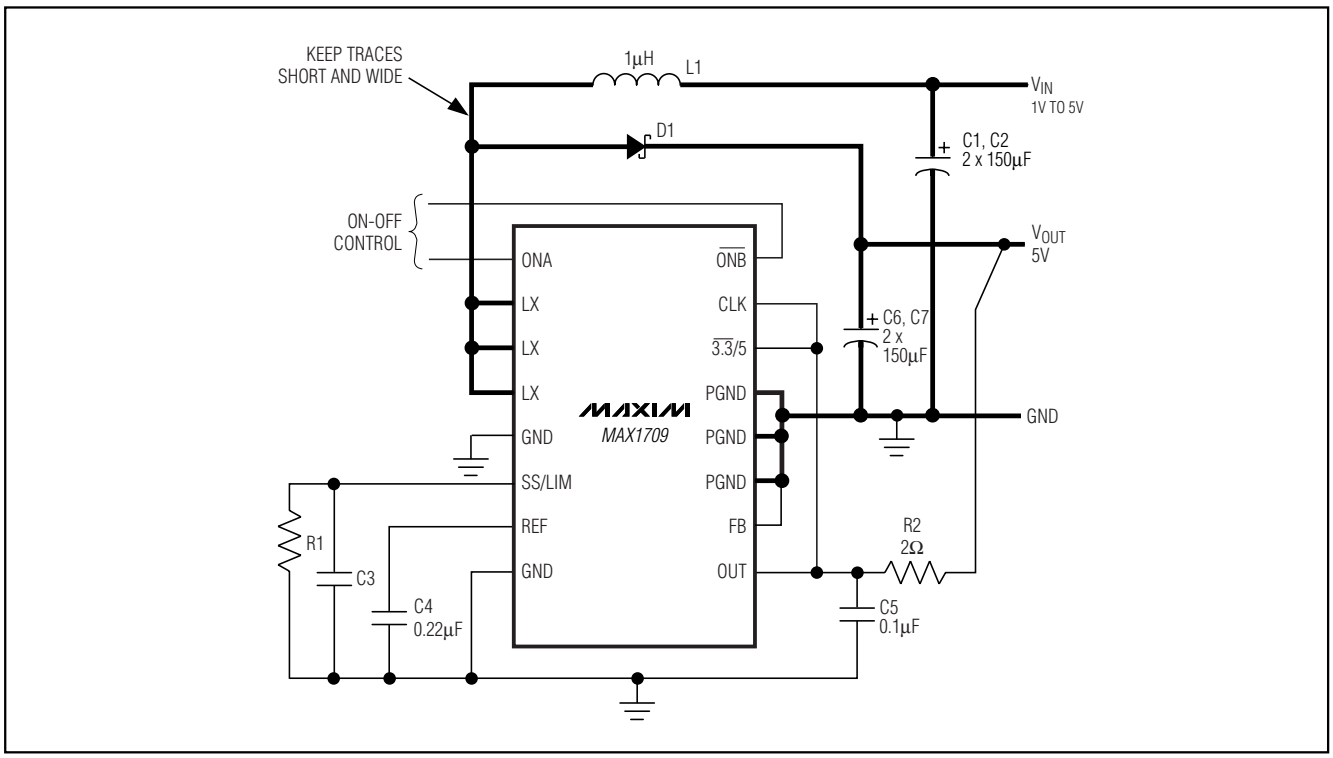

Figure 1. Standard Operating Circuit

Detailed Description

The MAX1709 step-up converter offers high efficiency and high integration for high-power applications. It operates with an input voltage as low as 0.7V and is suitable for single- to 3 cell battery inputs as well as 2.5V or 3.3V regulated supply inputs. The output voltage is preset to +3.3V or +5.0V or can be adjusted with external resistors for voltages between +2.5V to +5.5V.

The MAX1709 internal N-channel MOSFET switch is rated for 10A (RMS value) and can deliver loads to 4A, depending on input and output voltages. For flexibility, the current limit and soft-start rate are independently programmable.

A 600kHz switching frequency allows for a small inductor to be used. The switching frequency is also synchronizable to an external clock ranging from 350kHz to 1000kHz.

ONA, $\overline{ONB}$

The logic levels at ONA and $\overline{ONB}$ turn the MAX1709 on or off. When ONA = 1 or $\overline{ONB}$ = 0, the part is on. When ONA = 0 and $\overline{ONB}$ = 1, the part is off (Table 1). Logic high on control can be implemented by tying $\overline{ONB}$ high and using ONA for shutdown. Implement inverted single-line on/off control by grounding ONA and toggling $\overline{ONB}$. Implement momentary pushbutton On/Off as described in the *Applications Information* section. Both inputs have approximately 0.15V of hysteresis.

Switching Frequency

The MAX1709 switches at the fixed-frequency internal oscillator rate (600kHz) or can be synchronized to an external clock. Connect CLK to OUT for internal clock operation. Apply a clock signal to CLK to synchronize to an external clock. The frequency can be changed on the fly. The MAX1709 will synchronize to a new external clock rate in two cycles and will take approximately 40µs to revert to its internal clock frequency once the external clock pulses stop and CLK is driven high. Table 2 summarizes oscillator operation.

Operation

The MAX1709 switches at a constant frequency (600kHz) and modulates the MOSFET switch pulse width to control the power transferred per cycle and regulate the voltage across the load. In low-noise applications, the fundamental and the harmonics generated by the fixed switching frequency are easily filtered out. Figure 2 shows the simplified functional diagram for the MAX1709. Figure 3 shows the simplified PWM con-

Table 1. On/Off Logic Control

1	1	On

Table 2. Selecting Switching Frequency

CLK	MODE
0	Not allowed
1	PWM
External clock (350kHz–1000kHz)	Synchronized PWM

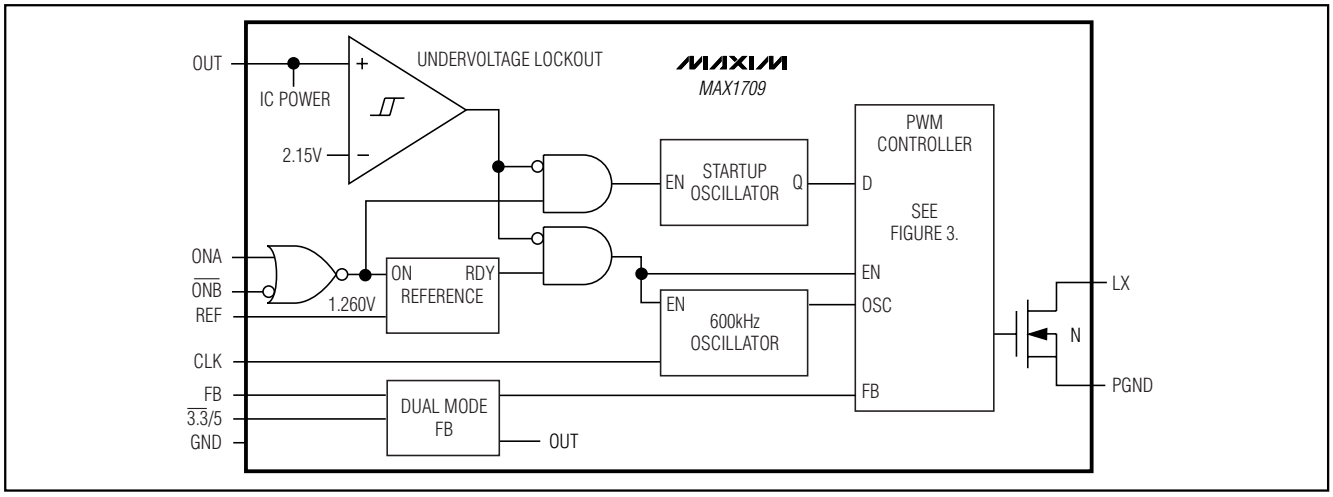

Figure 2. Simplified Functional Diagram

troller functional diagram. The MAX1709 enters synchronized current-mode PWM when a clock signal (350kHz < f_{CLK} < 1000kHz) is applied to CLK. For wireless or noise-sensitive applications, this ensures that switching harmonics are predictable and kept outside the IF frequency band(s). High-frequency operation permits low-magnitude output ripple voltage and minimum inductor and filter capacitor size. Switching losses will increase at the higher frequencies (see *Power Dissipation*).

Setting the Output Voltage

The MAX1709 features Dual Mode™ operation. When FB is connected to ground, the MAX1709 generates a fixed output voltage of either +3.3V or +5V, depending on the logic applied to the 3.3/5 input (Figure 1). The output can be configured for other voltages, using two external resistors as shown in Figure 4. To set the output voltage externally, choose an R3 value that is large enough to minimize load at the output but small enough to minimize errors due to leakage and the time constant to FB. A value of R4 ≤ 50kΩ is required.

$$R3 = R4\left(\frac{V_{OUT}}{V_{FB}} - 1\right)$$

where V_{FB} = 1.24V.

Soft-Start/Current-Limit Adjustment (SS/LIM)

The soft-start pin allows the soft-start time to be adjusted by connecting a capacitor from SS/LIM to ground. Select capacitor C3 (connected to SS/LIM pin) as:

$$C3\ (\text{in } \mu F) = 3.2 \times t_{SS}$$

where t_{SS} is the time (in seconds) it takes the switch current limit to reach full value.

To improve efficiency or reduce inductor size at reduced load currents, the current limit can be reduced from its nominal value (see *Electrical Characteristics*). A resistor (R1 in Figure 1) between SS/LIM and ground reduces the current limit as follows:

$$R1 = 312.5k\Omega \times \frac{I_1}{I_{LIM}} \left(R1 \le 312.5k\Omega\right)$$

Dual Mode is a trademark of Maxim Integrated Products.

where I_1 is the desired current limit in amperes, and I_{LIM} is the current limit value from the *Electrical Characteristics*.

Design Procedure

Inductor Selection (L1)

The MAX1709's high switching frequency allows the use of a small-size inductor. Use a 1.0µH inductor for 600kHz operation. If the MAX1709 will be synchronized at a different frequency, scale the inductor value with the inverse of frequency (L_1 = 1µH × 600kHz / f_{SYNC}). The PWM design tolerates inductor values within ±25% of this calculated value, so choose the closest standard inductor value. For example, use 1.5µH for 350kHz and 0.68µH for 1MHz).

Inductors with a ferrite core or equivalent are recommended; powder iron cores are not recommended for use at high switching frequencies. Ensure the inductor's saturation rating (the current at which the core begins to saturate and inductance falls) exceeds the internal current limit. Note that this current may be reduced through SS/LIM if less than the MAX1709's full load current is needed (see *Electrical Characteristics* for ratings). For highest efficiency, use a coil with low DC resistance, preferably under 10mΩ. To minimize radiated noise, use a toroid, pot core, or shielded inductor. See Tables 3 and 4 for a list of recommended components and component suppliers. To calculate the maximum output current (in amperes), use the following equation:

$$I_{OUT(MAX)} = D'\left(I_{LIM} - D'\left(\frac{V_{OUT} + V_D - V_{IN}}{2 \times f \times L1}\right)\right)$$

where:
V_{IN} = input voltage
V_D = forward voltage drop of the Schottky diode at I_{LIM} current
V_{OUT} = output voltage
D' = (V_{IN}) / (V_{OUT} + V_D), assuming switch voltage drop is negligible
f = switching frequency
L1 = inductor value

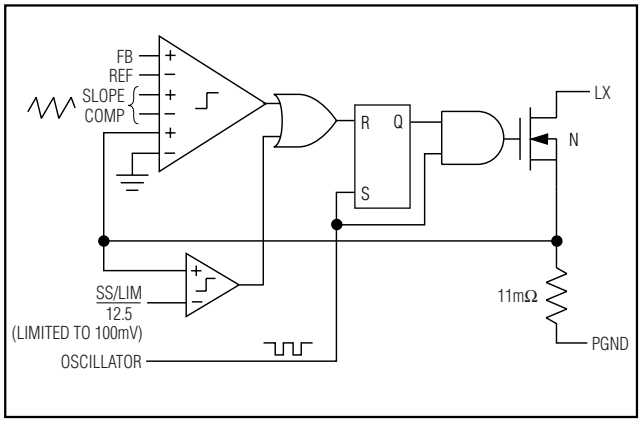

Figure 3. Simplified PWM Controller Functional Diagram

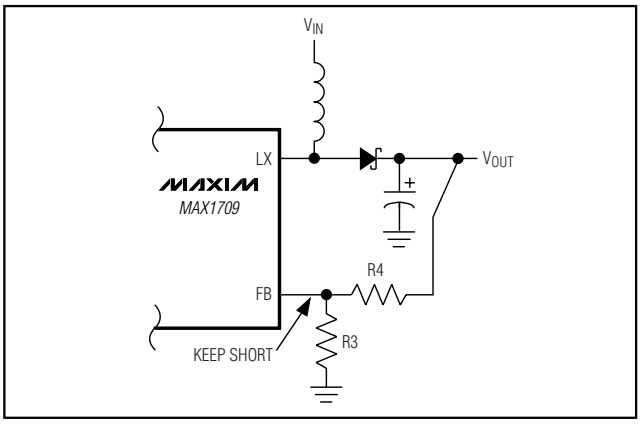

Figure 4. Adjustable Output Voltage

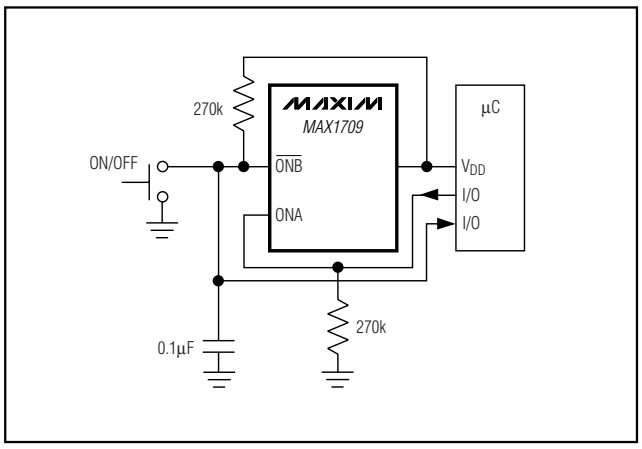

Figure 5. Momentary Pushbutton On-Off Switch

I_{LIM} = minimum value of switch current limit from *Electrical Characteristics* or set by $R_{SET/LIM}$.

Diode Selection (D1)

The MAX1709's high switching frequency demands a high-speed rectifier. Schottky diodes, such as the MBRD1035CTL or STPS8L30B (Table 3), are recommended. The diode's current rating must exceed the maximum load current, and its breakdown voltage must exceed V_{OUT}. The diode must be placed within 10mm of the LX switching node and the output filter capacitor. The diode also must be able to dissipate the power calculated by the following equation:

$$P_{DIODE} = I_{OUT} \times V_D$$

where I_{OUT} is the average load current and V_D is the diode forward voltage at the peak switch current.

Capacitor Selection

Input Bypass Capacitors (C1, C2)

Two 150µF, low-ESR tantalum input capacitors will reduce peak currents and reflected noise due to inductor current ripple. Lower ESR allows for lower input ripple current, but combined ESR values up to 50mΩ are acceptable. Smaller ceramic capacitors may also be used for light loads or in applications that can tolerate higher input current ripple.

Output Filter Capacitors (C6, C7)

The output filter capacitor ESR must be kept under 15mΩ for stable operation. Two parallel 150µF polymer capacitors (Panasonic EEFUE0J151R) typically exhibit 5mΩ of ESR. This translates to approximately 35mV of output ripple at 7A switch current. Bypass the MAX1709 IC supply input (OUT) with a 0.1µF ceramic capacitor to GND and a 2Ω series resistor (R2, as shown in Figure 1).

MAX1709 IC Power Dissipation

The major components of MAX1709 dissipated power are switch conductance loss (P_{SW}), capacitive loss (P_{CAP}), and switch transition loss (P_{TRAN}). Throughout the formulas, numerical examples are provided in {}, corresponding to the following condition:

$$\{V_{IN} = 3.3V,\ V_{OUT} = 5V,\ V_D = 0.5V,\ I_{OUT} = 4A\}$$

An important parameter to compute the power dissipated in the MAX1709 is the approximate peak switch current (I_{SW}):

$$I_{SW} = \frac{I_{OUT}}{D'} \qquad \{6.67A\}$$

$$D' = \frac{V_{IN}}{V_{OUT} + V_D} \qquad \{0.6\}$$

$$P_D\ (MAX1709) = P_{SW} + P_{CAP} + P_{TRAN} \qquad \{0.83W\}$$

$$P_{SW} = (1 - D')\ I_{SW}^2 \times R_{SW} \qquad \{0.59W\}$$

where:

R_{SW} = switch resistance {33mΩ}

$P_{CAP} = (C_{DIO} + CD_{SW} + CG_{SW})\ (V_{OUT} + V_D)^2 f$ {0.09W}

C_{DIO} = catch-diode capacitance {1000pF}
CD_{SW} = switch drain capacitance {2500pF}
CG_{SW} = switch gate capacitance {1500pF}
f = switching frequency {600kHz}

$P_{TRAN} = (V_{OUT} + V_D)\ I_{SW} \times t_{SW} \times f / 3$ {0.15W}

where t_{SW} = is switch turn-on or turn-off time {20ns}.

Applications Information

Using a Momentary On/Off Switch

A momentary pushbutton switch can be used to turn the MAX1709 on and off. As shown in Figure 5, when ONA is pulled low and $\overline{ONB}$ is pulled high, the part is off. When the momentary switch is pressed, $\overline{ONB}$ is pulled low and the regulator turns on. The switch should be on long enough for the microcontroller to exit reset. The controller issues a logic high to ONA, which guarantees that the part will stay on regardless of the subsequent switch state. To turn the regulator off, press the switch long enough for the controller to read the switch status and pull ONA low. When the switch is released, $\overline{ONB}$ pulls high and the regulator turns off.

Layout Considerations

Due to high inductor current levels and fast switching waveforms, proper PC board layout is essential. Protect sensitive analog grounds by using a star ground config-

4A, Low-Noise, High-Frequency, Step-Up DC-DC Converter

uration. Connect PGND, the input bypass capacitor ground lead, and the output filter capacitor ground lead to a single point (star ground configuration). In addition, minimize trace lengths to reduce stray capacitance and trace resistance, especially from the LX pins to the catch diode (D1) and output capacitors (C6 and C7) to PGND pins. If an external resistor-divider is used to set the output voltage (Figure 4), the trace from FB to the resistors must be extremely short and must be shielded from switching signals, such as CLK or LX. Refer to a layout example in the MAX1709EVKIT data sheet.
